Fig 4: Caesar cipher script executed successfully in VS Code terminal, demonstrating the first working encryption module of the toolkit.

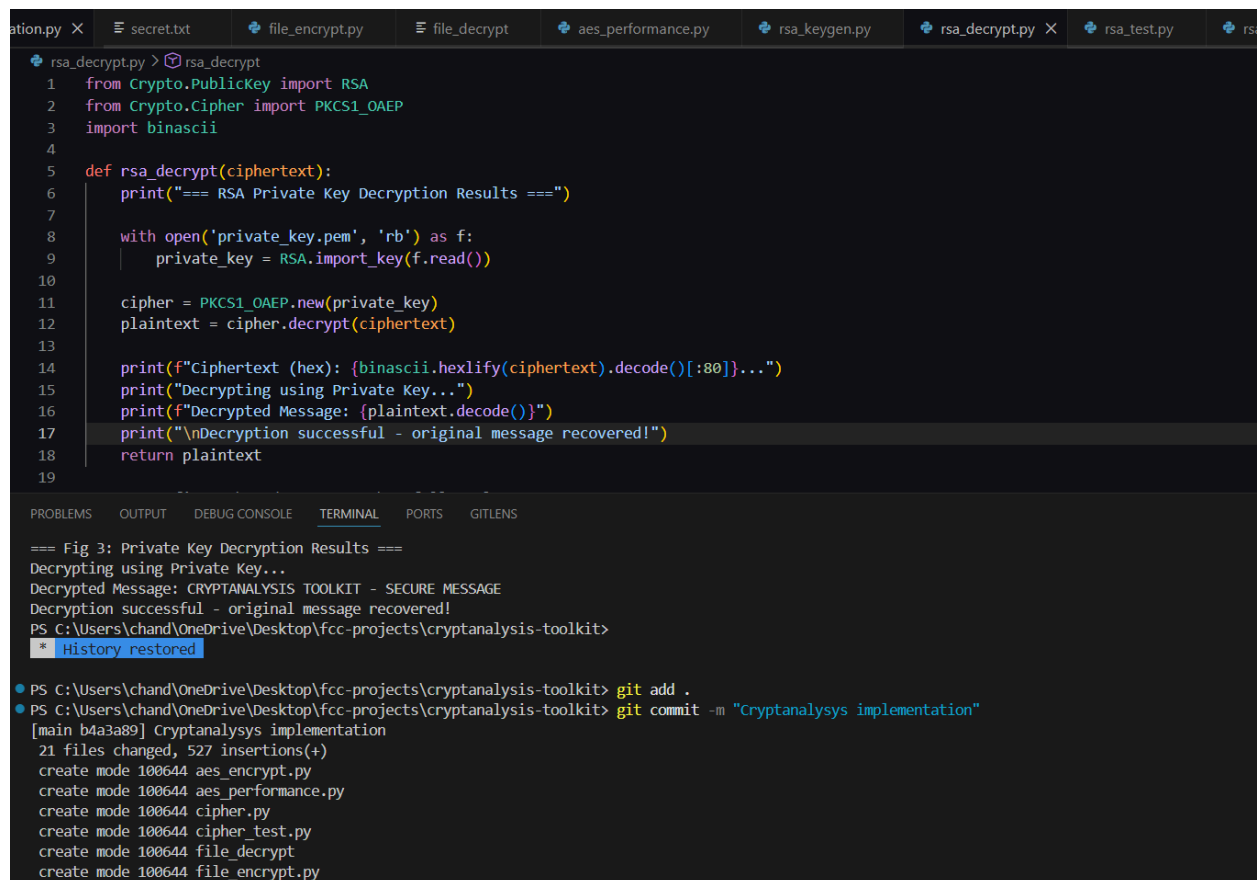

The image shows a Visual Studio Code editor window with a file named `caesar.py`. The script defines a `caesar_cipher` function that takes `text` and `shift` as arguments. It iterates through each character in `text`, checking if it is an alphabet character. If it is, it calculates a new character based on the shift value, wrapping around the alphabet. If it is not an alphabet character, it leaves the character unchanged. The script then uses this function to encrypt the message "CRYPTANALYSIS TOOLKIT" with a shift of 3, printing both the original and encrypted messages.

```
1 def caesar_cipher(text, shift):
2     result = ""
3     for char in text:
4         if char.isalpha():
5             shift_base = 65 if char.isupper() else 97
6             result += chr((ord(char) - shift_base + shift) % 26 + shift_base)
7         else:
8             result += char
9     return result
10
11 message = "CRYPTANALYSIS TOOLKIT"
12 encrypted = caesar_cipher(message, 3)
13 print(f"Original: {message}")
14 print(f"Encrypted: {encrypted}")
15
16
17
```

The terminal output shows the execution of the script three times, each time using the command `python caesar.py`. The first two executions show the original message "CRYPTANALYSIS TOOLKIT" and the encrypted message "FUBSWDQDOBVLV WRRONLW". The third execution shows the original message "CRYPTANALYSIS TOOLKIT" and the encrypted message "FUBSWDQDOBVLV WRRONLW".

Student Reflection

This week I configured my cryptography development environment and implemented a Caesar cipher script. Setting up Git and pushing to GitHub proved challenging, particularly resolving the master/main branch conflict. I gained hands-on experience with VS Code, PyCryptodome, OpenSSL, and GitHub, understanding how these tools support secure cryptographic development workflows.

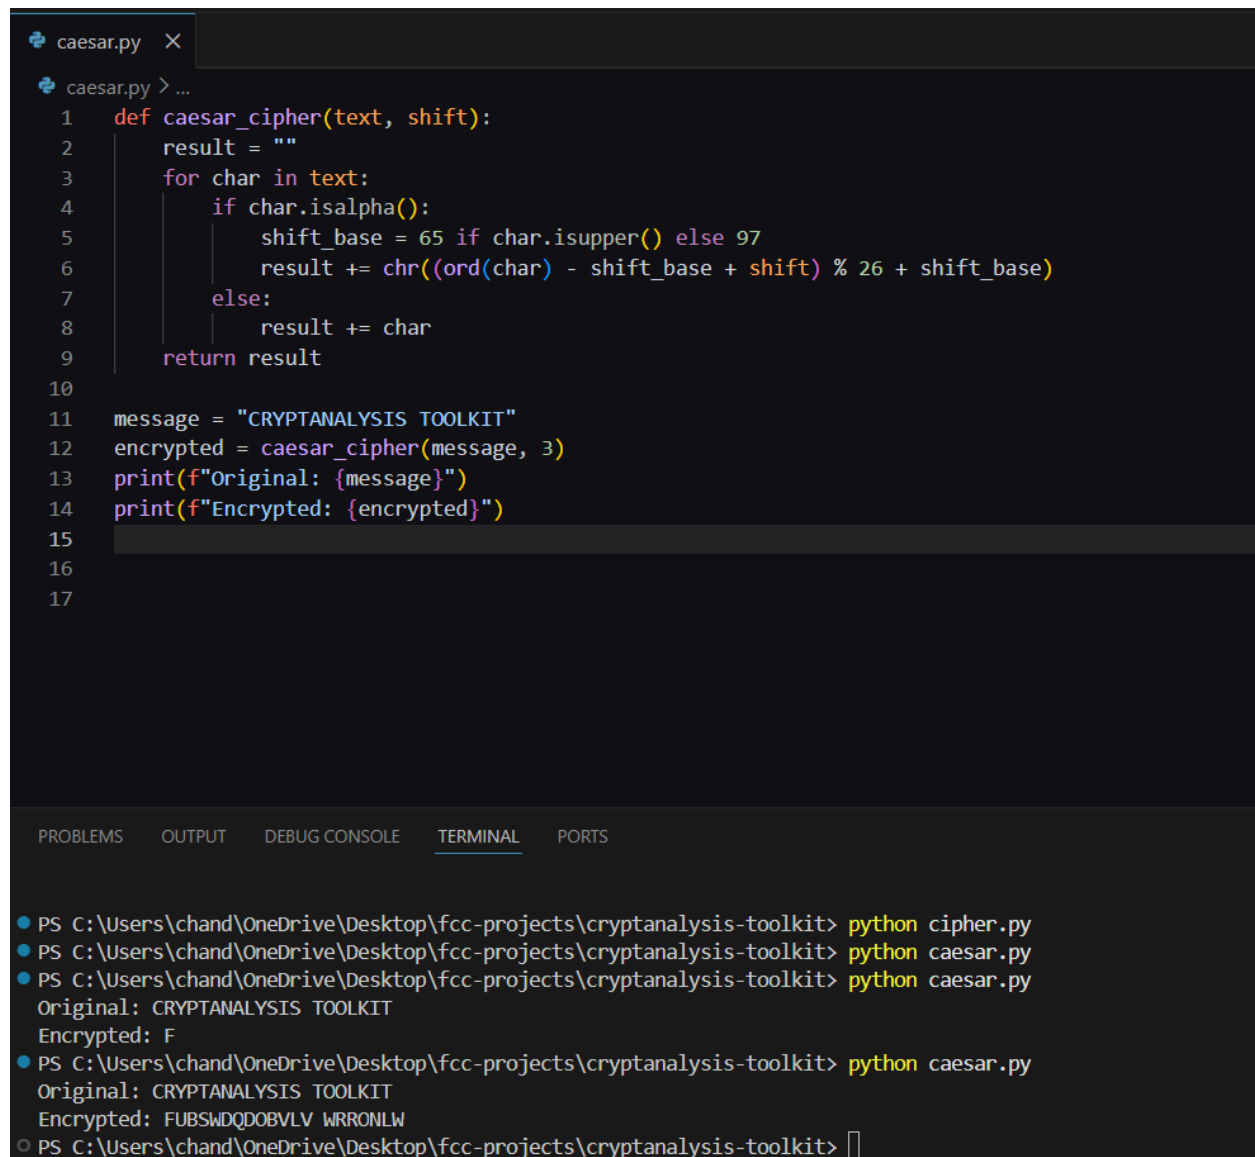

Week 1 Summary

Week 1 involved setting up the cryptography development environment, installing Python, VS Code, OpenSSL and cryptographic libraries. A Caesar cipher script was successfully implemented and pushed to GitHub, establishing the foundation for the Cryptanalysis and Security Testing Toolkit.

Week 2: Classical Cryptography and Cipher Design

Implementation of Classical Encryption Algorithms

Fig 1: Caesar cipher implementation displayed in VS Code, showing the shift-based substitution encryption logic forming the first module of the toolkit.

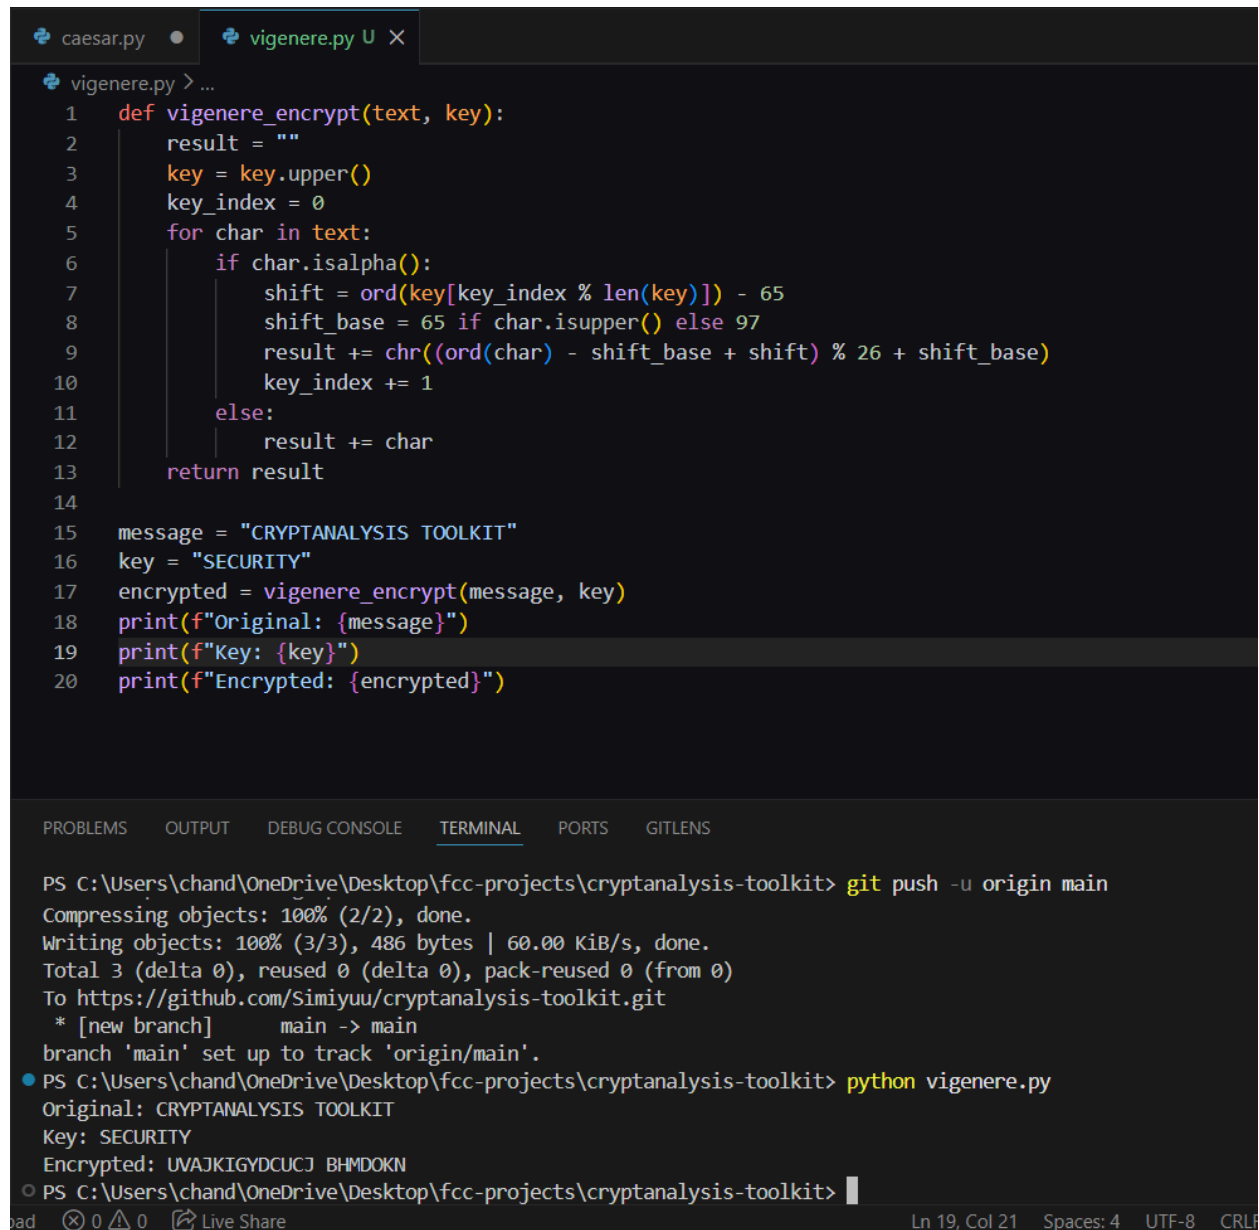

```
caesar.py X
caesar.py > ...
1  def caesar_cipher(text, shift):
2      result = ""
3      for char in text:
4          if char.isalpha():
5              shift_base = 65 if char.isupper() else 97
6              result += chr((ord(char) - shift_base + shift) % 26 + shift_base)
7          else:
8              result += char
9      return result
10
11 message = "CRYPTANALYSIS TOOLKIT"
12 encrypted = caesar_cipher(message, 3)
13 print(f"Original: {message}")
14 print(f"Encrypted: {encrypted}")
15

Student Reflection

Caesar and Vigenère ciphers both substitute plaintext letters with ciphertext letters using different key mechanisms. The key is critical since encryption algorithms are publicly known, making the key the only secret. Caesar cipher's 25 possible shifts make it vulnerable to brute force attacks, while Vigenère's keyword provides stronger but still breakable protection.

Week 2 Summary

Week 2 involved implementing Caesar and Vigenère cipher modules for the toolkit. Both ciphers demonstrated substitution-based encryption with key-dependent security. Caesar cipher was identified as weak due to its small key space, while Vigenère offered improved but still vulnerable polyalphabetic encryption.

Week 3: Stream Ciphers and Randomness Testing

Implementation of Stream Ciphers Systems and Random Sequence Analysis

Fig 1: LFSR generator implementation displayed in VS Code, showing the feedback logic and tap configuration used to generate pseudorandom binary sequences.

```
caesar.py • vigenere.py U cipher.py U cipher_test.py U lfsr.py U •
lfsr.py > ...
1 def lfsr(seed, taps, length):
2     state = seed
3     sequence = []
4     for _ in range(length):
5         feedback = 0
6         for tap in taps:
7             feedback ^= (state >> tap) & 1
8         sequence.append(state & 1)
9         state = (state >> 1) | (feedback << (len(bin(seed)) - 3))
10    return sequence
11
12    seed = 0b1011
13    taps = [3, 1]
14    sequence = lfsr(seed, taps, 20)
15    print("=== LFSR Generator ===")
16    print(f"Seed: {bin(seed)}")
17    print(f"Taps: {taps}")
18    print(f"Generated Sequence: {sequence}")
```

Fig 2: Pseudorandom binary sequence successfully generated using the LFSR, displaying seed value, tap positions, and the resulting 20-bit output sequence.

The image shows a Visual Studio Code editor window with a Python file named `lfsr.py` open. The file contains a function `lfsr` that generates a pseudorandom binary sequence using a Linear Feedback Shift Register (LFSR). The function takes a seed, taps, and a length as arguments. It initializes a state and a sequence, then iterates to generate the sequence by shifting the state and applying feedback from the specified taps. The output is a list of 20 bits.

```
1 def lfsr(seed, taps, length):
2     state = seed
3     sequence = []
4     for _ in range(length):
5         feedback = 0
6         for tap in taps:
7             feedback ^= (state >> tap) & 1
8         sequence.append(state & 1)
9         state = (state >> 1) | (feedback << (len(bin(seed)) - 3))
10    return sequence
11
12 seed = 0b1011
13 taps = [3, 1]
14 sequence = lfsr(seed, taps, 20)
15 print("=== LFSR Generator ===")
16 print(f"Seed: {bin(seed)}")
17 print(f"Taps: {taps}")
18 print(f"Generated Sequence: {sequence}")
```

The terminal output shows the execution of the script, displaying the seed, taps, and the resulting 20-bit sequence.

=== Encryption Performance Test ===
Caesar Cipher Time: 0.4644 ms
RC4 Stream Cipher Time: 1.0886 ms

Conclusion: RC4 operates at byte level making it faster for larger data.
○ PS C:\Users\chand\OneDrive\Desktop\fcc-projects\cryptanalysis-toolkit>
```

Student Reflection

Randomness is critical in cryptography since an algorithm is only as secure as it is unpredictable. RC4 generates a keystream by scrambling a 256-value array using the secret key, producing unique bytes through pointer swapping. Statistical and performance tests confirmed RC4 produces strong randomness and encrypts faster than Caesar cipher.

Week 3 Summary

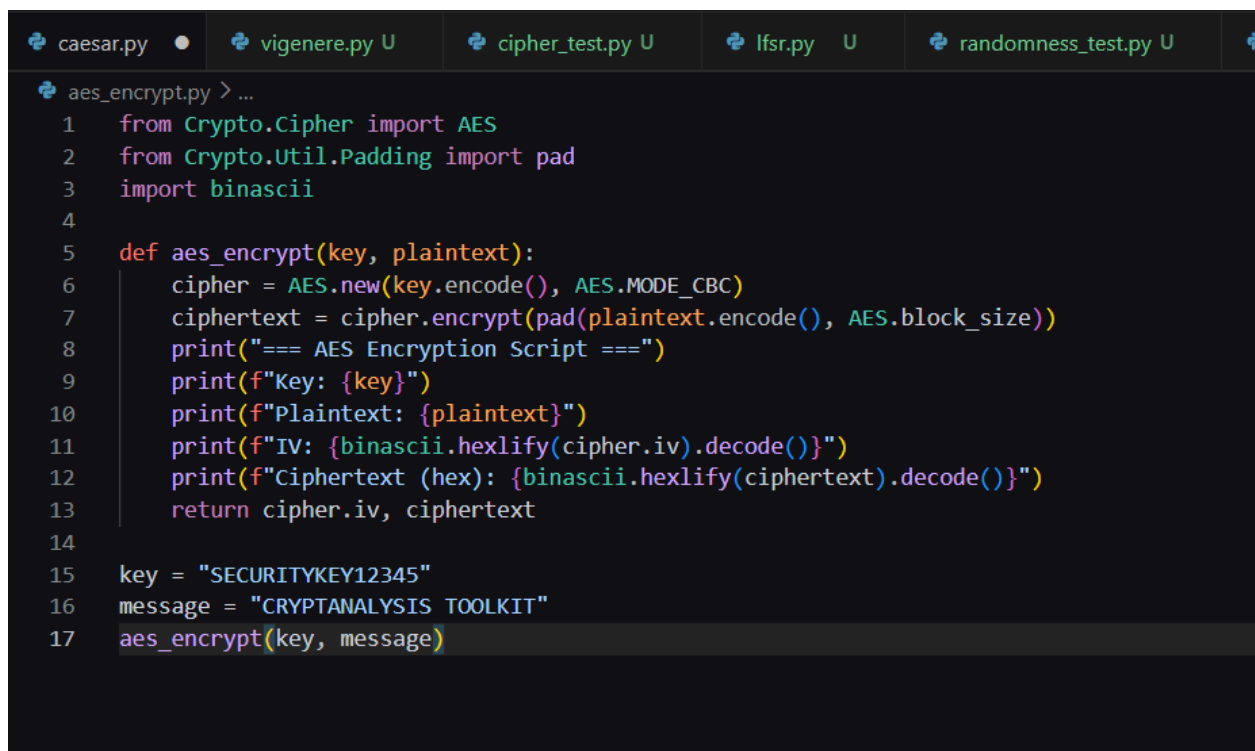

Week 3 involved implementing an LFSR pseudorandom generator and RC4 stream cipher module for the toolkit. Frequency, Runs and Mean statistical tests validated randomness quality

of generated sequences. Performance testing confirmed RC4 significantly outperforms Caesar cipher, demonstrating the efficiency advantages of stream cipher encryption.

Week 4: Block Cipher Design and AES

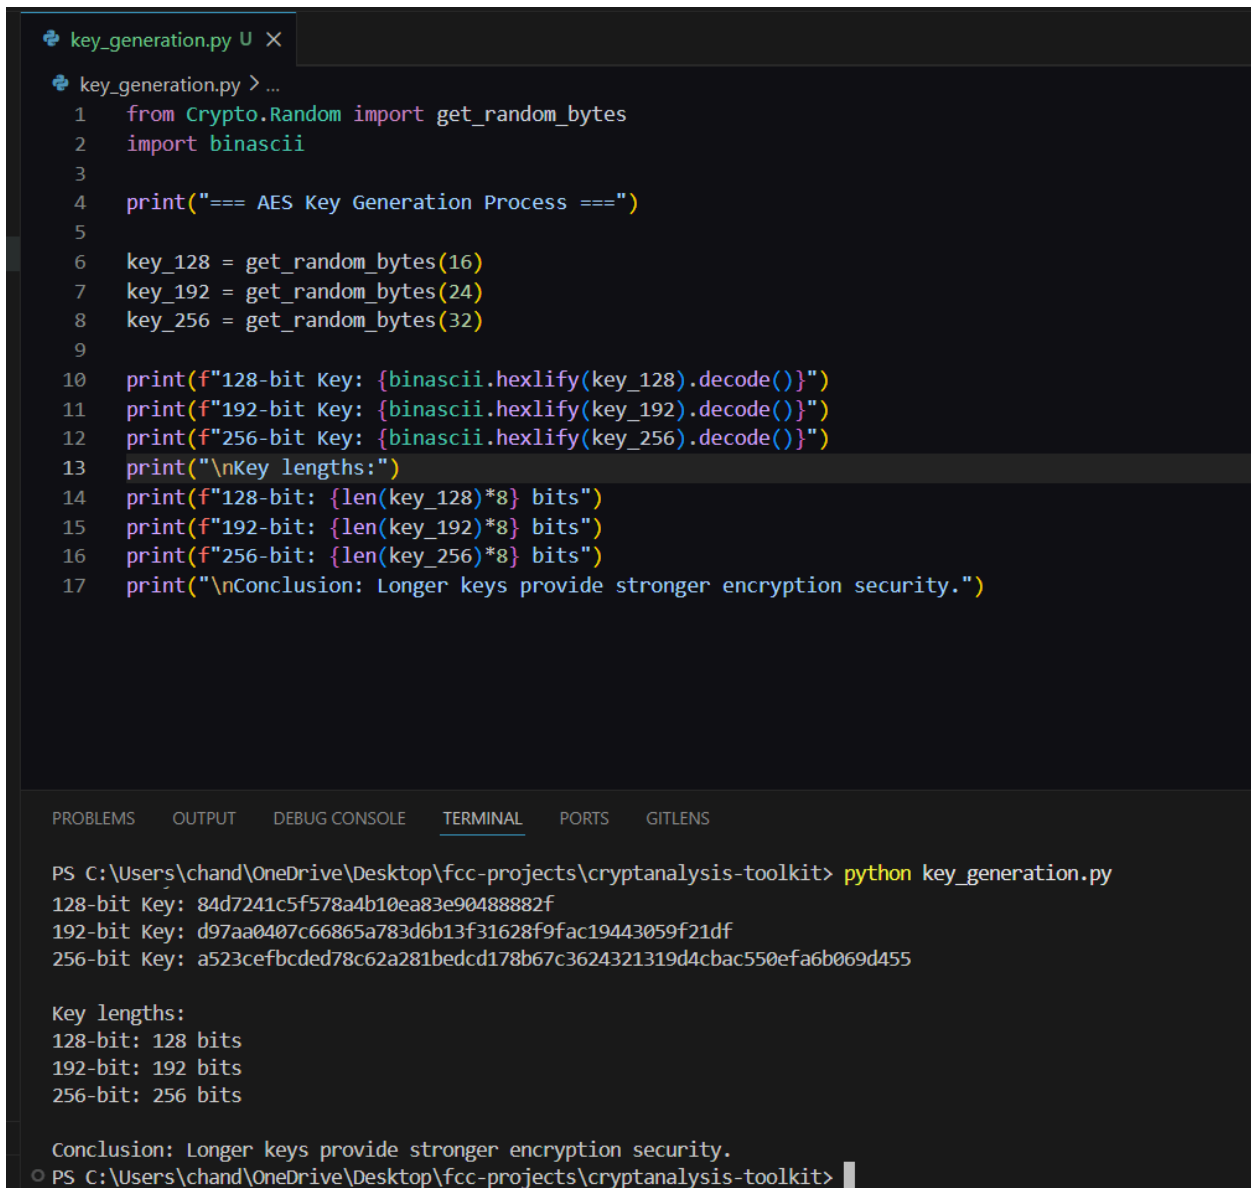

Advanced Encryption Standard (AES) and Block Cipher Operations

Fig 5: AES performance test results displayed, showing encryption times across four message sizes confirming AES maintains strong and consistent performance at scale.

The screenshot shows a VS Code editor with a file named `aes_performance.py` open. The script defines an `aes_encrypt` function and tests it with four message sizes: 100, 1000, 10000, and 100000 characters. The output in the terminal shows the execution results, including the time taken for each encryption and the resulting speed in characters per second. The conclusion states that AES maintains strong performance across varying data sizes.

```
3 from Crypto.Util.Padding import pad
4 from Crypto.Random import get_random_bytes
5

1000 chars        0.5269 ms     1897875 chars/sec
10000 chars       0.4060 ms     24628914 chars/sec
100000 chars      1.8506 ms     54036382 chars/sec

Conclusion: AES maintains strong performance across varying data sizes.
PS C:\Users\chand\OneDrive\Desktop\fcc-projects\cryptanalysis-toolkit>
```

Student Reflection

AES operates as a block cipher, chopping data into fixed chunks and processing them through 10 rounds of mathematical scrambling using expanded round keys. The IV ensures identical messages produce different ciphertext every time. Encryption and decryption were successfully implemented, though the performance test across large message sizes took considerable processing time.

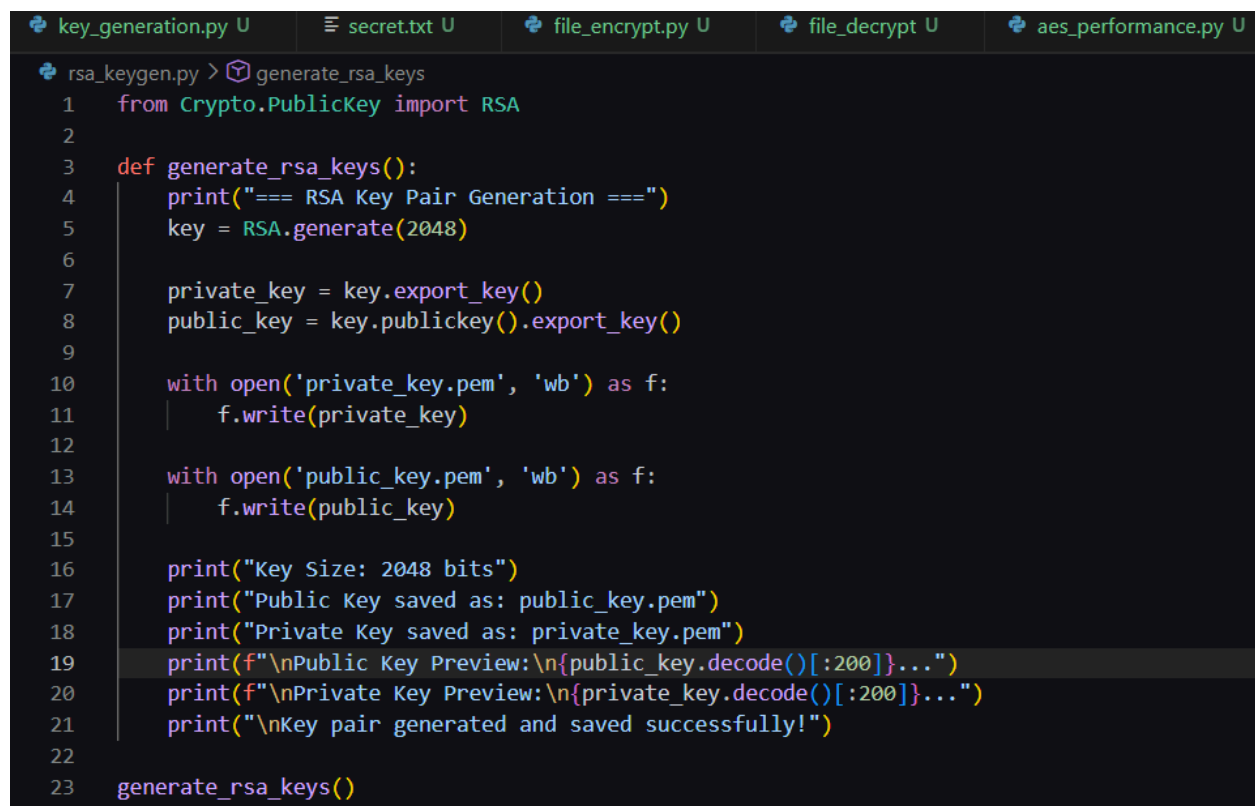

Week 4 Summary

Week 4 involved implementing AES encryption and decryption modules using CBC mode with random IV generation and PKCS padding. Key scheduling was explored showing how AES expands one master key into 11 round keys. Performance testing across varying message sizes confirmed AES maintains strong encryption despite increased processing time at scale.

Week 5: Public Key Cryptography (RSA)

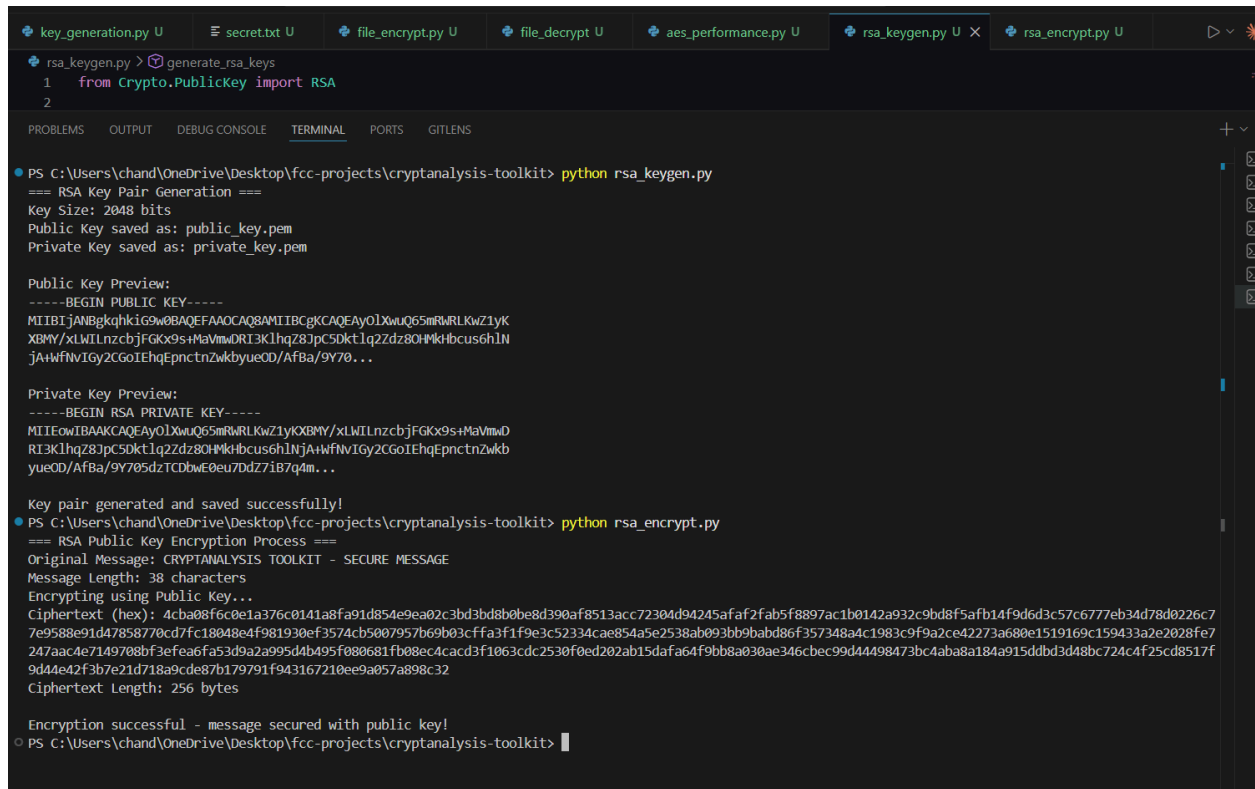

Implementation of RSA Encryption and Key Management

Fig 1: RSA key pair generation script displayed in VS Code, showing 2048-bit key generation logic with public and private keys saved as PEM files.

```
key_generation.py U  secret.txt U  file_encrypt.py U  file_decrypt U  aes_performance.py U
rsa_keygen.py > generate_rsa_keys
1  from Crypto.PublicKey import RSA
2
3  def generate_rsa_keys():
4      print("=== RSA Key Pair Generation ===")
5      key = RSA.generate(2048)
6
7      private_key = key.export_key()
8      public_key = key.publickey().export_key()
9
10     with open('private_key.pem', 'wb') as f:
11         f.write(private_key)
12
13     with open('public_key.pem', 'wb') as f:
14         f.write(public_key)
15
16     print("Key Size: 2048 bits")
17     print("Public Key saved as: public_key.pem")

Student Reflection

Unlike symmetric encryption which uses one key for both locking and unlocking, RSA uses mathematically linked public and private keys. The public key encrypts like an open padlock, once shut only the private key can open it. RSA's security relies on prime number factorization, validated through key generation, encryption and performance tests.

Week 5 Summary

Week 5 involved implementing RSA asymmetric encryption, simulating secure message transmission between sender and receiver. A 2048-bit key pair was generated with public key encryption and private key decryption successfully demonstrated. A full validation suite confirmed correct key generation, accurate encryption and decryption, and acceptable performance across multiple test cases.

Creativity Section: Frequency Analysis Visualizer

Letter Frequency Analysis Tool Cryptanalysis Extension Module

As an extension to the Cryptanalysis and Security Testing Toolkit, a Frequency Analysis Visualizer was implemented using Python and Matplotlib. Frequency analysis is a real-world cryptanalysis technique used to break classical ciphers by exploiting the uneven distribution of letters in natural language. This module adds an offensive analysis capability to the toolkit going beyond the standard weekly assignments.

Fig 1: Frequency Analysis Script

A screenshot of a code editor showing a Python script named 'frequency_analysis.py'. The script is designed to perform a letter frequency analysis on a given ciphertext. It starts by importing 'matplotlib.pyplot' as 'plt' and 'string'. A function 'frequency_analysis(ciphertext)' is defined, which takes a ciphertext string as input. Inside the function, the ciphertext is converted to uppercase, and a frequency dictionary is created. A loop iterates over the ASCII uppercase letters, counting their occurrences in the ciphertext. The total number of letters is calculated, and a dictionary of percentages is generated. The script then prints the results in a formatted way, showing the letter and its percentage. Finally, a bar chart is created using Matplotlib, with the x-axis labeled 'Letters' and the y-axis labeled 'Frequency (%)'. The chart is titled 'Letter Frequency Analysis - Cryptanalysis Toolkit' and is saved as 'frequency_analysis.png' before being displayed.

```
secret.txt file_encrypt.py file_decrypt aes_performance.py rsa_keygen.py rsa_decrypt.py
frequency_analysis.py > frequency_analysis
1 import matplotlib.pyplot as plt
2 import string
3
4 def frequency_analysis(ciphertext):
5     ciphertext = ciphertext.upper()
6     frequency = {}
7
8     for letter in string.ascii_uppercase:
9         frequency[letter] = ciphertext.count(letter)
10
11     total = sum(frequency.values())
12     percentages = {k: (v/total)*100 for k, v in frequency.items()}
13
14     print("=== Frequency Analysis Results ===")
15     for letter, percent in percentages.items():
16         bar = "█" * int(percent)
17         print(f"{letter}: {bar} {percent:.2f}%")
18
19     plt.figure(figsize=(14, 6))
20     plt.bar(percentages.keys(), percentages.values(), color='red')
21     plt.title('Letter Frequency Analysis - Cryptanalysis Toolkit')
22     plt.xlabel('Letters')
23     plt.ylabel('Frequency (%)')
24     plt.grid(axis='y', linestyle='--', alpha=0.7)
25     plt.tight_layout()
26     plt.savefig('frequency_analysis.png')
27     plt.show()
28     print("\nSecret saved as frequency_analysis.png")
```

Fig 2: Terminal Frequency Output

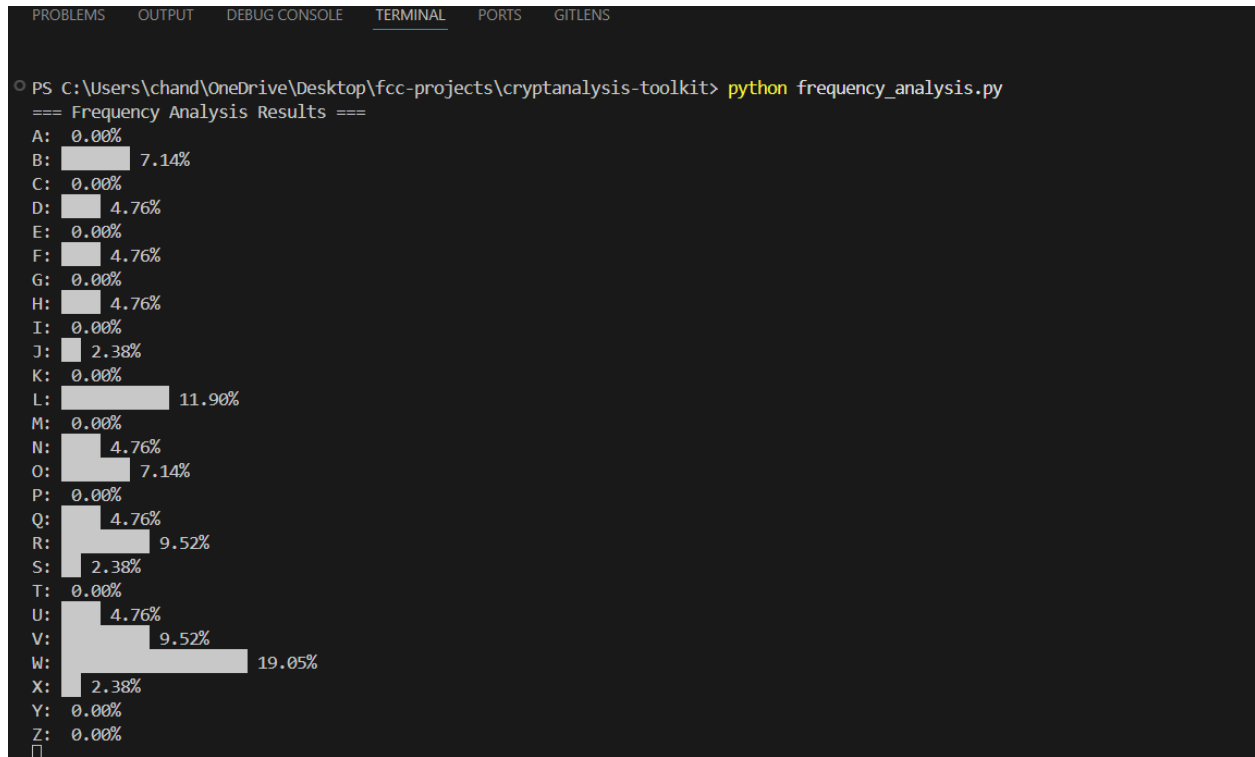

Fig 3: Matplotlib Bar Chart Visualization

Creativity Reflections

The frequency analysis visualizer extends the toolkit with a real cryptanalysis attack technique. By plotting letter distributions in ciphertext, patterns become visible that can be exploited to break classical ciphers. This demonstrates how attackers identify weaknesses in substitution ciphers, reinforcing the importance of stronger modern encryption algorithms.

WEEK 6: Symmetric Ciphers II – Substitution-Permutation Networks (SPN), S-Boxes and Non-Linearity

14          11                   0                NO
15          10                   7                NO

Total Matches: 1/16
Non-Linearity Score: 93.8%
Result: STRONG S-Box – High non-linearity confirmed!

=== Why Non-Linearity Matters ===
Linear transformations can be expressed as simple equations.
Attackers exploit linear patterns to recover secret keys.
S-Boxes with high non-linearity resist algebraic attacks.
The AES S-Box achieves maximum non-linearity of 112 out of 128.
PS C:\Users\chand\OneDrive\Desktop\fcc-projects\cryptanalysis-toolkit\week6-spn> 
```

Practical Task 3: SPN Security Evaluation

Fig 3: SPN vs Feistel Security Evaluation

The screenshot shows a code editor with a file explorer on the left and a terminal window on the right. The file explorer lists files under 'CRYPTANALYSIS-TOOLKIT', including 'week6-spn' and 'spn_vs_feistel.py'. The terminal window shows the execution of the script, which performs a performance test, a structure comparison, and a security evaluation.

```
week6-spn > spn_vs_feistel.py > ...
37 def evaluate():
61     print("-" * 65)
62     print(f"{'Data Processing':<30} {'Half block':<20} {'Full block'}")
63     print(f"{'Decryption':<30} {'Same structure':<20} {'Inverse operations'}")
64     print(f"{'Non-Linearity':<30} {'Round function':<20} {'S-Box based'}")
65     print(f"{'Modern Example':<30} {'DES':<20} {'AES'}")
66     print(f"{'Rounds Needed':<30} {'More rounds':<20} {'Fewer rounds'}")
67
```

OUTPUT PROBLEMS DEBUG CONSOLE TERMINAL PORTS GITLENS

```
PS C:\Users\chand\OneDrive\Desktop\fcc-projects\cryptanalysis-toolkit> cd week6-spn
PS C:\Users\chand\OneDrive\Desktop\fcc-projects\cryptanalysis-toolkit\week6-spn> python spn_vs_feistel.py
=== SPN vs Feistel Security Evaluation ===

[PERFORMANCE TEST] (10000 encryptions)
Feistel Encryption Time: 126.3766 ms
SPN Encryption Time: 69.2284 ms

[STRUCTURE COMPARISON]
Property      Feistel      SPN
-----
Data Processing  Half block   Full block
Decryption      Same structure  Inverse operations
Non-Linearity   Round function  S-Box based
Modern Example   DES          AES
Rounds Needed   More rounds   Fewer rounds

[SECURITY EVALUATION]
Feistel Result: {feistel_encrypt(plaintext, key)}
SPN Result:     {spn_encrypt(plaintext, key)}

Conclusion: SPN processes the full block each round,
providing stronger diffusion than Feistel structures.

```

Student Reflection

An SPN repeatedly applies substitution, permutation and key mixing to convert plaintext into ciphertext. S-Boxes introduce non-linearity by substituting values through lookup tables, preventing attackers from expressing transformations as simple equations. Unlike Feistel ciphers which split data in half, SPNs process the entire block at once providing stronger diffusion per round.
